

Voltage protection pnp and npn

Pnp works by when increasing the voltage beyond Voltage Zener more than breakdown it lets the transistor(1) works forcing transistor(2) to turn off causing no current through load so $V=0$ while npn works by the voltage divider concept by adjust the values of the most left resistors we can control the transistors and the same concept

The difference:

It all lays on configurations as shown In the videos simple example is the base and emitter configurations
